Noninvasive Evaluation of Coronary Collateral Arterial Flow by Coronary Computed Tomographic Angiography

Jin-Ho Choi, MD, PhD*; Eun Kyoung Kim, MD*; Sung Mok Kim, MD, PhD; Young Bin Song, MD, PhD; Joo-Yong Hahn, MD, PhD; Seung Hyuk Choi, MD, PhD; Hyeon-Cheol Gwon, MD, PhD; Sang Hoon Lee, MD, PhD; Yeon Hyeon Choe, MD, PhD; Jae K. Oh, MD

Background—Coronary collateral flow is an alternative source of myocardial perfusion in patients with totally occluded coronary arteries. Clinical evaluation of collateral flow has been limited by the need of invasive measurements. We investigated whether noninvasive coronary computed tomographic angiography can evaluate the angiographic extent of coronary collateral flow.

Methods and Results—We enrolled 325 coronary computed tomographic angiography cases with angiographically confirmed chronic total occlusion (median age, 63 years; men 83%). Transluminal attenuation gradient (TAG), which reflects the kinetics of contrast media in coronary artery, of an entire artery as well as of a distal vessel was assessed to evaluate the flow in entire vessel and distal vessel. TAGs were validated against visually assessed angiographic collateral connection and Rentrop grading. TAG of an entire artery increased consistently according to the angiographic extent of collateral flow (P<0.001). Well-developed collaterals, defined by highest collateral connection and Rentrop grades (n=103), could be predicted by TAG of an entire artery (cutoff, ≥7.6 Hounsfield units/10 mm; c-statistics, 0.72; sensitivity, 65%; specificity, 73%; positive predictive value, 52%; negative predictive value, 82%). TAG of a distal vessel could discriminate the antegrade (n=143) and retrograde (n=182) flows in distal artery (cutoff, 0.0 Hounsfield units/10 mm; c-statistics, 0.88; sensitivity, 78%; specificity, 85%; positive predictive value, 87%; negative predictive value, 75%).

Key Words: collateral circulation ▪ coronary artery disease ▪ multidetector computed tomography

Coronary collateral vessels are anastomotic channels between major epicardial coronary arteries and develop as an adaptation to myocardial ischemia.1-3 In the setting of acute myocardial infarction, patients with developed coronary collaterals had less infarct size, ventricular remodeling, and ventricular dysfunction compared with patients without collaterals.4-7 Well-developed collaterals have shown long-term survival benefit in both patients with stable angina and patients with acute myocardial infarction.8,9 Despite the clinical importance, clinical evaluation of collaterals has been limited by the need of invasive measurements.10-13

The contrast media filling of coronary artery lumen is manifested as radiological attenuation in coronary computed tomographic (CT) angiography. Recently, studies have shown that transluminal attenuation gradient (TAG), an intracoronary luminal attenuation assessed from coronary CT angiography, reflects the kinetics of contrast media in coronary artery.14-16 TAG demonstrated the feasibility for noninvasive assessment of hemodynamically significant coronary arterial stenosis and flow.17-20

We hypothesized that the concept of intraluminal contrast media kinetics could also be applied to totally occluded vessel supplied by collateral flow. We measured TAG of totally occluded coronary arteries and validated it with the functional extent and direction of collateral flow determined by invasive coronary angiography.

Clinical Perspective on p 490

The contrast media filling of coronary artery lumen is manifested as radiological attenuation in coronary computed tomographic (CT) angiography. Recently, studies have shown that transluminal attenuation gradient (TAG), an intracoronary luminal attenuation assessed from coronary CT angiography, reflects the kinetics of contrast media in coronary artery.14-16 TAG demonstrated the feasibility for noninvasive assessment of hemodynamically significant coronary arterial stenosis and flow.17-20

We hypothesized that the concept of intraluminal contrast media kinetics could also be applied to totally occluded vessel supplied by collateral flow. We measured TAG of totally occluded coronary arteries and validated it with the functional extent and direction of collateral flow determined by invasive coronary angiography.

Methods

Patients

From June 2006 and February 2013, we consecutively screened 623 patients who showed ≥1 totally occluded coronary artery by clinically indicated coronary CT angiography and validated by
Coronary Collateral Flow Evaluation by CT

Choi et al

Coronary CT angiography showed at least one chronic total occlusion (CTO) in coronary artery, and confirmed by subsequent invasive coronary angiography within 8 weeks (N=623)

Clinical history:
- Prior history of bypass surgery (N=29)
- Prior history of attempted PCI for CTO (N=3)
- Non-ST elevation myocardial infarction before coronary angiography (N=6)

Coronary CT angiography revealed:
- Inadequate images due to severe diffuse coronary calcification or poor contrast opacification (N=33)

Invasive coronary angiography revealed:
- CTO in small vessel (diameter <2mm) or branches (N=22)
- Total occlusion caused by in-stent restenosis (N=2)
- Subtotal occlusion (diameter stenosis > 99%, TIMI 1 antegrade flow, N=124)
- Severely occlusive lesion (diameter stenosis 90 – 99%, TIMI 2 or TIMI 3 antegrade flow, N=17)
- Coronary vasospasm (N=27)

Coronary CT angiography acquisition
- FLASH technique was used (N=33)

Enrolled into study (N=325)

Figure 1. Patients with ≥1 total occlusion in major coronary artery by clinically indicated coronary computed tomographic (CT) angiography were validated by subsequent diagnostic coronary angiography <8 wk. Patients with angiographic subtotal occlusion or inadequate images were excluded. A total of 33 cases acquired by ultrafast spiral flash 128-slice CT scanner was excluded to avoid bias related to axial scan time between 64- and 128-slice CT scanners. CTO indicates chronic total occlusion; PCI, percutaneous coronary intervention; and TIMI, Thrombolysis in Myocardial Infarction.
Circ Cardiovasc Imaging  May 2014

6 to 8 seconds in both 64- and 128-slice scanners. Cardiovascular radiologists interpreted the images on a dedicated workstation (iNtuition; Terarecon, Foster City, CA).

Transluminal Attenuation Gradient
TAG was assessed as described previously. In brief, cross-sectional images perpendicular to the vessel centerline were reconstructed for each major coronary artery. Luminal cross-sectional area (in mm²) and radiological attenuation (in HU) were measured at 5-mm intervals from the ostium (TAG of an entire artery, TAGall) or just distal to CTO segment (TAG of a distal vessel, TAGdistal) where the vessel cross-sectional area fell <2.0 mm². TAGall and TAGdistal were devised to reflect the flow in the whole vessel and flow in distal vessel, respectively. The contour of the region of interest and the vessel centerline were manually corrected if necessary. TAG was defined as the linear regression coefficient between measured intraluminal radiological attenuation (in HU) and vessel length (per 10 mm; Figure 2).

Coronary Angiography
Coronary angiography was performed using standard techniques with the use of intracoronary nitroglycerin. Collateral flow was assessed by 2 experienced interventional cardiologists blinded to other imaging data. In case of disagreement, a third cardiologist was invited to reach an agreement. The diameter and angiographic flow of collateral vessels were semiquantitatively assessed using the collateral connection grade (0=no continuous connection; 1=continuous thread-like connection; 2=continuous and small branch-like connection) and the Rentrop grade (0=no visible filling of collaterals; 1=filling of side branches; 2=partial filling of epicardial segment; 3=complete filling of epicardial segment). Well-developed collateral was defined by collaterals having both collateral connection grade 2 and Rentrop.

Figure 2. The concept of transluminal attenuation gradient (TAG) for the evaluation of coronary artery flow. Arrows indicate the extent and direction of flow. A to D, Coronary arteries with stenosis but without total occlusion. TAG of an entire artery (TAGall) decreases according to the severity of coronary artery stenosis. E to H, Coronary arteries with total occlusion. TAGall reflects the whole coronary artery flow and converges to 0 according to the functional extent of collateral flow. TAG of a distal vessel (TAGdistal) reflects both the function and direction of distal artery flow. TAGdistal has positive or negative value according to the direction of collateral flow. The absolute value of TAGdistal is higher in poorly developed collateral than in well-developed collateral.
grade 3. The direction of collateral flow in distal artery was visually determined by the most predominating flow.

Statistical Analysis
Analysis was performed on a per-patient basis unless indicated otherwise. Continuous variables are compared between groups using Mann–Whitney U or Kruskal–Wallis test. Relationships between continuous variables among ordinal groups were tested by Jonckheere–Terpstra test for trend. Optimal cutoff of variables was estimated by Youden J statistics. The predictive performance of variables was calculated and compared with each other by receiver operating characteristics analysis and DeLong method. The inter-rater agreement and reproducibility of TAG and collateral grading were validated in 21 randomly selected vessels using Bland–Altman analysis and Cohen weighted κ. R version 3.0.1 (R Foundation for Statistical Computing, Vienna, Austria) was used. A 2-tailed P <0.05 was considered statistically significant.

Results

Patients
The median age of study population was 63 years, and 83% of patients were men. The majority of patients had stable angina or silent ischemia (91%) and also had multivessel disease (70%). Two-dimensional echocardiography was performed in 318 patients (98%). Regional wall abnormality was found in 188 patients (58%), but most patients showed preserved left ventricular systolic function (Table 1).

Reproducibility and Agreement of Measurements
By Bland–Altman analysis, the intrarater and inter-rater limits of agreement of TAG were 0.5 HU/10 mm (95% confidence interval [CI], −0.2 to 1.3) and −0.2 HU/10 mm (95% CI, −1.1 to 0.8). Weighted κ for intrarater and inter-rater variability was 0.83 (95% CI, 0.65–1.00) and 0.78 (95% CI, 0.58–0.98) for Rentrop grade; 0.79 (95% CI, 0.60–0.98) and 0.79 (95% CI, 0.59–0.98) for collateral connection grade; and 0.82 (95% CI, 0.58–1.00) and 0.91 (95% CI, 0.74–1.00) for direction of collaterals.

Assessment of the Functional Extent and Direction of Collateral Flow by Invasive Coronary Angiography
Half of the total occlusion was found in right coronary artery (n=157; 48%). The directions of flow in distal artery were antegrade in 178 vessels (44%) and retrograde in 228 vessels (56%). Well-developed collateral was found in 103 vessels (32%) and showed mostly retrograde flow in distal artery (n=75; 73%; Table 2).

Assessment of the Functional Extent of Collateral Flow by TAG
Representative cases are shown in Figure 3A to 3D. TAG all increased consistently according to the angiographic Rentrop grade. TAG in distal artery was also compared with that in proximal artery. The differences between TAG in proximal artery and distal artery were 0.3 HU/mm by Rentrop grade 1 (p=0.59), 0.4 HU/mm by Rentrop grade 2 (p=0.003), and 0.8 HU/mm by Rentrop grade 3 (p=0.001).

*In case of multiple total occlusions (n=42; 13%), total occlusion in most dominating vessel was used.
†Well-developed collateral is defined by collaterals showing both Rentrop grade 3 and collateral connection grade 2. Most of vessels with well-developed collaterals showed retrograde flow in distal artery (73%).
Figure 3. Representative cases of noninvasive collateral flow evaluation. Curved or straight multiplanar reconstruction of coronary computed tomographic (CT) angiography, invasive coronary angiography (CAG), and the results of transluminal attenuation gradient (TAG) are shown. Red dotted line indicates direction of collateral flow; white dotted line, chronic total occlusion (CTO) segment; yellow arrowhead, vessel distal to CTO; pink arrowhead, collateral vessels; green graph, intraluminal attenuation; blue arrow, TAG of an entire artery; and pink arrow, TAG of a distal vessel. Movies of CAG and CT showing collateral vessels are available in the Data Supplement. A, CTO at mid left anterior descending coronary artery (LAD) and septal collateral with Rentrop grade 2, collateral connection grade 1 antegrade flow (see Movies I–III in the Data Supplement). B, CTO at mid LAD and right ventricular (RV) branch collateral with Rentrop grade 2, collateral connection grade 1 retrograde flow (see Movies IV–VI in the Data Supplement). C, CTO at proximal LAD and collateral between posterolateral (PL) branch and diagonal branch with Rentrop grade 3, collateral connection grade 2 antegrade flow (see Movies VII–IX in the Data Supplement). D, CTO at proximal right coronary artery (RCA) and apical collateral with Rentrop grade 3, collateral connection grade 2 retrograde flow (see Movies X–XII in the Data Supplement). PDA indicates posterior descending; and HU, Hounsfield unit.
grade or collateral connection grade ($P<0.001$ by Kruskal–Wallis and Jonckheere–Terpstra test; all; Figure 4A and 4B). $\text{TAG}_{\text{all}}$ showed moderate predictive performance for well-developed collateral: optimal cutoff, $>−7.6$ HU/10 mm; sensitivity, 65.1% (95% CI, 55.0–74.2%); specificity, 72.5% (95% CI, 66.1–78.3%); positive predictive value, 52.3% (95% CI, 43.3–61.2%); negative predictive value, 81.7% (95% CI, 75.6–86.9%); and $c$-statistics, 0.720 (95% CI, 0.667–0.768).

### Assessment of the Direction of Flow in Distal Artery by TAG

Vessels with retrograde flow in distal artery showed significantly higher $\text{TAG}_{\text{distal}}$ compared with vessels with antegrade flow in distal artery ($P<0.001$ by Mann–Whitney test; Figure 5A). $\text{TAG}_{\text{distal}}$ showed fair predictive performance for retrograde flow in distal artery: optimal cutoff, $>0.0$ HU/10 mm; sensitivity, 77.5% (95% CI, 70.7–83.3%); specificity, 85.3% (95% CI, 78.4–90.7%); positive predictive value, 87.0% (95% CI, 80.9–91.8%); negative predictive value, 74.8% (95% CI, 67.4–81.3%); and $c$-statistics, 0.875 (95% CI, 0.834–0.909).
The results of TAG all and TAGdistal in relation to the functional extent of collateral flow were different according to the direction of flow in distal artery. TAGall increased consistently according to the Rentrop grade or collateral connection grade irrespective of the direction of collateral flow. TAGdistal of vessels with antegrade flow in distal artery was mostly negative in value and also increased according to the Rentrop grade or collateral connection grade (P<0.01 by Kruskal–Wallis and Jonckheere–Terpstra test; all; Figure 6A–6D). However, TAG distal of vessels with retrograde flow in distal artery was mostly positive in value and showed a tendency of decrease according to Rentrop grade or collateral connection grade (P<0.05 by Kruskal–Wallis; P>0.05 by Jonckheere–Terpstra test; all; Figure 6E–6H).

Figure 6. A to D, Transluminal attenuation gradient of an entire artery, which reflects the functional extent of collateral flow, increased consistently according to the Rentrop grade or collateral connection grade in both antegrade and retrograde flow subgroups (P<0.01 by Kruskal–Wallis and Jonckheere–Terpstra test; all). JT indicates Jonckheere–Terpstra test; and KW, Kruskal–Wallis test. E to H, TAG of a distal vessel (TAGdistal), which reflects the direction of flow in distal vessel, was negative or positive in vessels with antegrade or retrograde flow, respectively. TAGdistal converged to 0 according to the Rentrop grade or collateral connection grade (P<0.05 by KW; all; P<0.05 by JT in E and F). HU indicates Hounsfield unit.
Discussion

Our study is the first of its kind to evaluate coronary collateral circulation by coronary CT angiography. Intracoronary attenuation-based analyses of CT enabled noninvasive functional assessment of coronary collateral flow and discrimination of the flow direction. Angiographically well-developed collateral vessels could also be predicted reasonably.

Well-developed collaterals are protective from myocardial ischemia, mitigate myocardial infarct, and improve survival.4–9 The presence of well-developed collaterals resulted in 36% reduced long-term mortality risk compared with poorly developed collaterals.24 Therefore, the evaluation of collateral flow would be important for long-term risk stratification in patients with total occlusion. Coronary CT angiography has been established for stenosis and functional imaging and showed high prognostic value for the prediction of future cardiovascular events.17–19,25–27 However, coronary CT angiography has not provided evaluation of collaterals mostly because of the limited spatial and temporal resolution.3 TAG can be measured in conventional 64-slice or higher CT scanners without additional radiation exposure, modification of CT acquisition protocols, or any sophisticated computational process.17–20 Therefore, TAG may extend the capability of coronary CT angiography into the evaluation of collateral flow and may improve the prognostic value of coronary CT angiography. The potential benefits of noninvasive collateral imaging now seem warranted.

Despite the improved procedural success and long-term vessel patency enabled by novel techniques and drug-eluting stents, CTO still remains a major challenge in current percutaneous coronary interventions, and the benefits of CTO revascularization are also in debate.29,30 Considering the potential procedural complications and nonnegligible radiation dose that may be offset by an intrinsically protective role of well-developed collateral vessels, selective revascularization of CTOs subtending a large amount of viable myocardium or those having collateral circulation insufficient to prevent ischemia may be a reasonable approach. Additional evaluation of collateral flow by TAG to the standard interpretation of coronary CT angiography may refine the evaluation of complex coronary circulation in patients with CTO.31,32

TAG_all and TAG_distal showed similar patterns for both well-developed collateral and retrograde flow in distal artery. It is explained by the fact that most (73%) well-developed collateral flow showed retrograde flow in distal artery. Our result also explains how CTO could be predicted by the reversed attenuation gradient in distal vessel, which corresponds to negative TAG_distal in our study.33

Limitations

Our results represent single-center experience. Half of the patients with potential for CTO were excluded after coronary angiography, because noninvasive discrimination between CTO and subtotal occlusion is frequently challenging.33 TAG was compared with semiquantitative angiographic collateral assessment, which correlates weakly with invasively assessed collateral flow index.22 TAG was investigated in a cross-sectional study and was not validated against long-term clinical results. The potential effects of a non-CTO lesion on collateral flow, multiple collateral vessels, or nonflat nature of intracoronary time–density curve were not addressed by the current study. Although TAG has been successfully studied from CT images with multiple cardiac cycles, the lack of temporal uniformity might affect our results.7,15 Single-beat imaging using scanners capable of entire coronary tree coverage would be a better methodology to validate TAG against coronary collateral physiology.16,20

Conclusions

TAG, an intracoronary attenuation-based analysis of coronary CT angiography, could reflect the functional extent and direction of coronary collateral flow. Additional studies are needed to validate the potential of noninvasive collateral flow assessment against invasive measurement and clinical benefit.

**CLINICAL PERSPECTIVE**

Total occlusion of coronary artery is not uncommon in patients with coronary artery disease. Myocardium subtended by totally occluded coronary artery is supplied by alternative source of blood flow named collateral vessels. In such patients, well-developed coronary collaterals are protective from myocardial ischemia, mitigate myocardial infarct, and improve survival. Despite the clinical importance, clinical evaluation of collaterals has been limited by the need of invasive measurements. Here we showed that intracoronary attenuation-based analyses of coronary computed tomographic angiography acquired by conventional 64-slice or higher computed tomographic scanners enables noninvasive functional assessment of coronary collateral flow. Additional functional evaluation of collateral flow to the standard interpretation of coronary computed tomographic angiography may refine evaluation and risk stratification of coronary circulations in patients with totally occluded coronary arteries.
